

## CHAPTER 14.1-3

### BAYESIAN NETWORKS

- ◊ Parameterized distributions
- ◊ Semantics
- ◊ Syntax

## Outline

A simple, graphical notation for conditional independence assertions and hence for compact specification of full joint distributions

In the simplest case, conditional distribution represented as

a directed, acyclic graph (link  $\approx$  "directly influences")

a set of nodes, one per variable

a conditional distribution for each node given its parents:

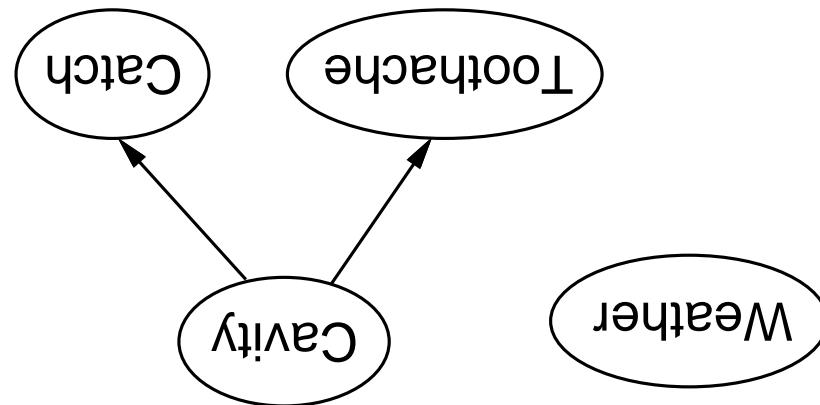

$P(X_i | \text{Parents}(X_i))$

In the simplest case, conditional distribution over  $X^i$  for each combination of parent values

## Bayesian networks

*Toothache* and *Catch* are conditionally independent given *Cavity*

*Weather* is independent of the other variables

Topology of network encodes conditional independence assertions:

Example

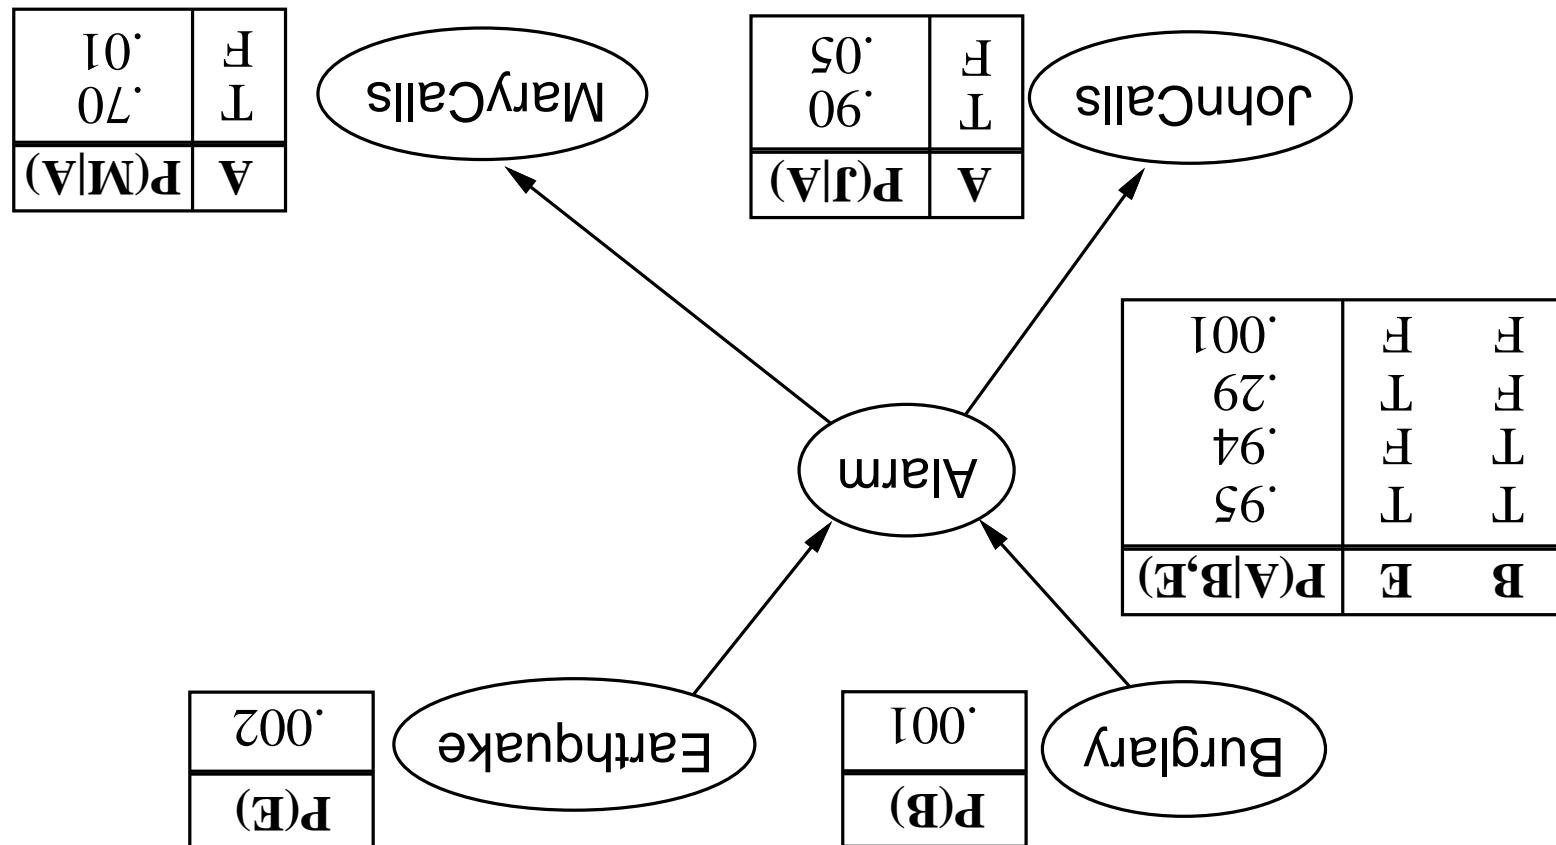

I'm at work, neighbor John calls to say my alarm is ringing, but neighbor Mary doesn't call. Sometimes it's set off by minor earthquakes. Is there a burglar?

Variables: *Burglar*, *Earthquake*, *Alarm*, *JohnCalls*, *MaryCalls*

Network topology reflects "causal" knowledge:

- A burglar can set the alarm off
- An earthquake can set the alarm off
- The alarm can cause Mary to call
- The alarm can cause John to call

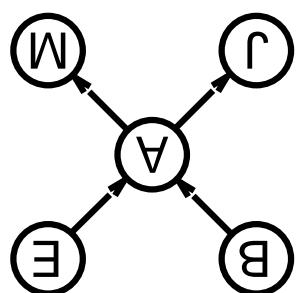

## Example

Example cont'd.

A CPT for Boolean  $X^i$  with  $k$  Boolean parents has  $2^k$  rows for the combinations of parent values

Each row requires one number for  $X^i = \text{true}$  (the number for  $X^i = \text{false}$  is just  $1 - p$ )

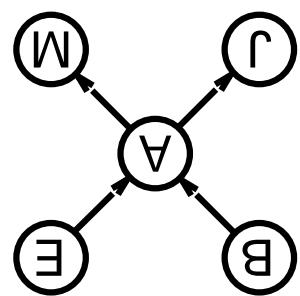

If each variable has no more than  $k$  parents, the complete network requires  $O(n \cdot 2^k)$  numbers

i.e., grows linearly with  $n$ , vs.  $O(2^n)$  for the full joint distribution

For burglary net,  $1 + 1 + 4 + 2 + 2 = 10$  numbers (vs.  $2^5 - 1 = 31$ )

## Compactness

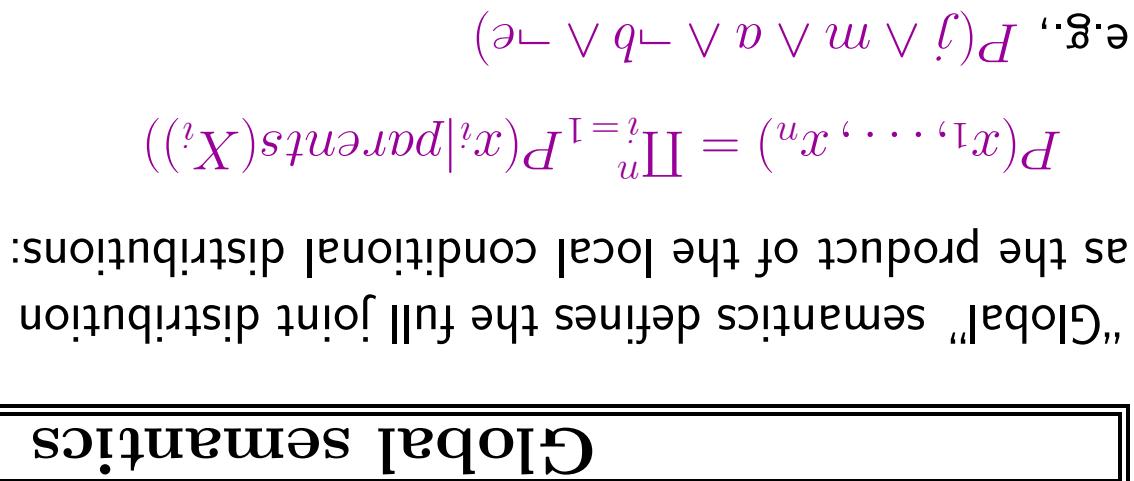

Global semantics defines the full joint distribution as the product of the local conditional distributions:

$$P(x_1, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

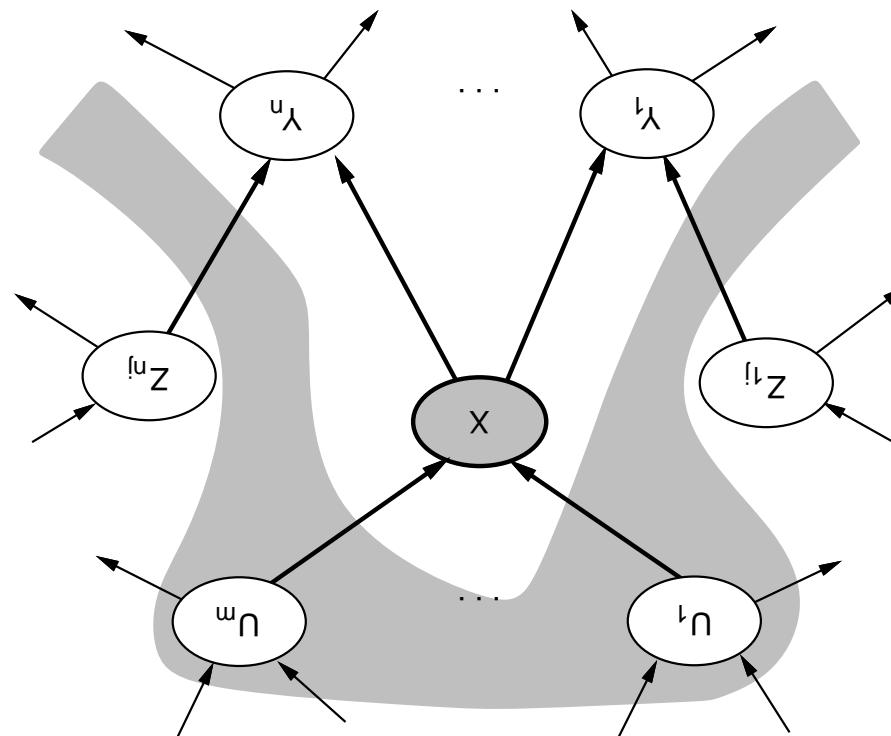

$$\text{e.g., } P(j \vee m \vee a \vee \neg b \vee \neg e)$$

=

**Global semantics**

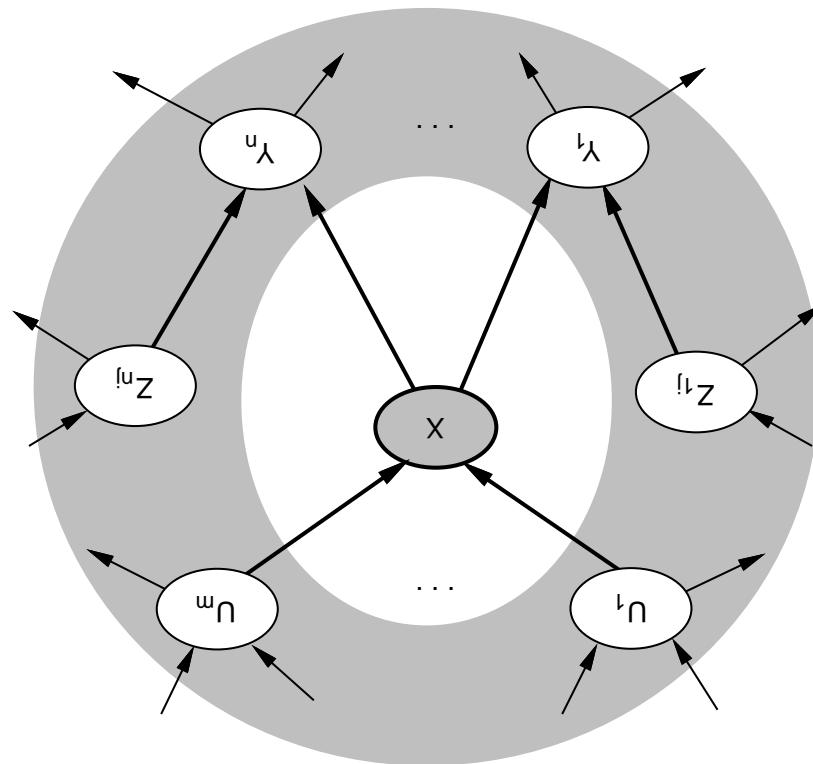

Theorem: Local semantics  $\Leftrightarrow$  global semantics

Local semantics: each node is conditionally independent  
of its nondescendants given its parents

Local semantics

Each node is conditionally independent of all others given its  
Markov blanket: parents + children + children's parents

Markov blanket

$$\mathbf{P}(X_1, \dots, X_u) = \prod_{i=1}^u \mathbf{P}(X_i | X_1, \dots, X_{i-1}) \quad (\text{chain rule})$$

$$= \prod_{i=1}^u \mathbf{P}(X_i | \text{Parents}(X_i)) \quad (\text{by construction})$$

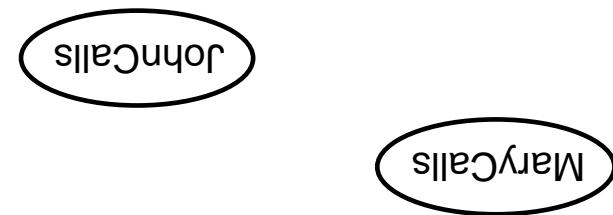

This choice of parents guarantees the global semantics:

- 1. Choose an ordering of variables  $X_1, \dots, X_u$
- 2. For  $i = 1$  to  $u$ 
  - add  $X_i$  to the network
  - select parents from  $X_1, \dots, X_{i-1}$  such that
  - $\mathbf{P}(X_i | \text{Parents}(X_i)) = \mathbf{P}(X_i | X_1, \dots, X_{i-1})$

Need a method such that a series of locally testable assertions of conditional independence guarantees the required global semantics

## Constructing Bayesian networks

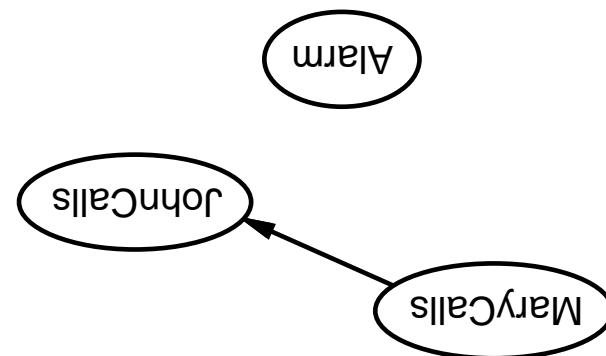

$$\dot{c}(f)D = (W|f)D$$

Suppose we choose the ordering  $M, f, A, B, E$

## Example

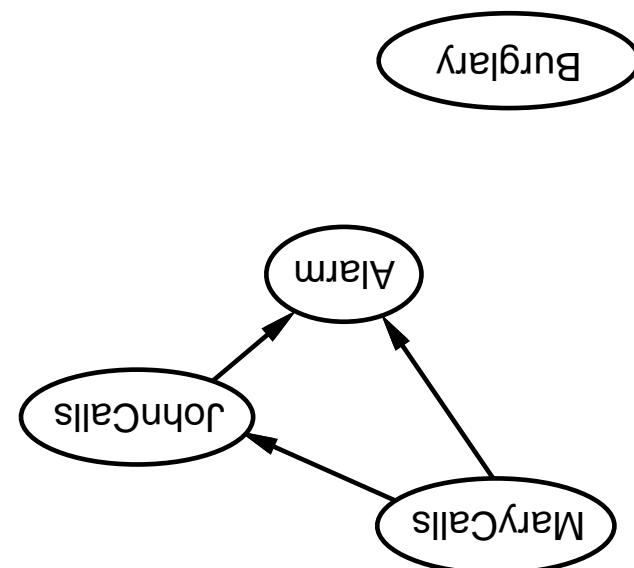

$P(A|T, M) = P(T|M)P(A|T)$  No  $P(M|T) = P(T|M)P(M)$

Suppose we choose the ordering  $M, J, A, B, E$

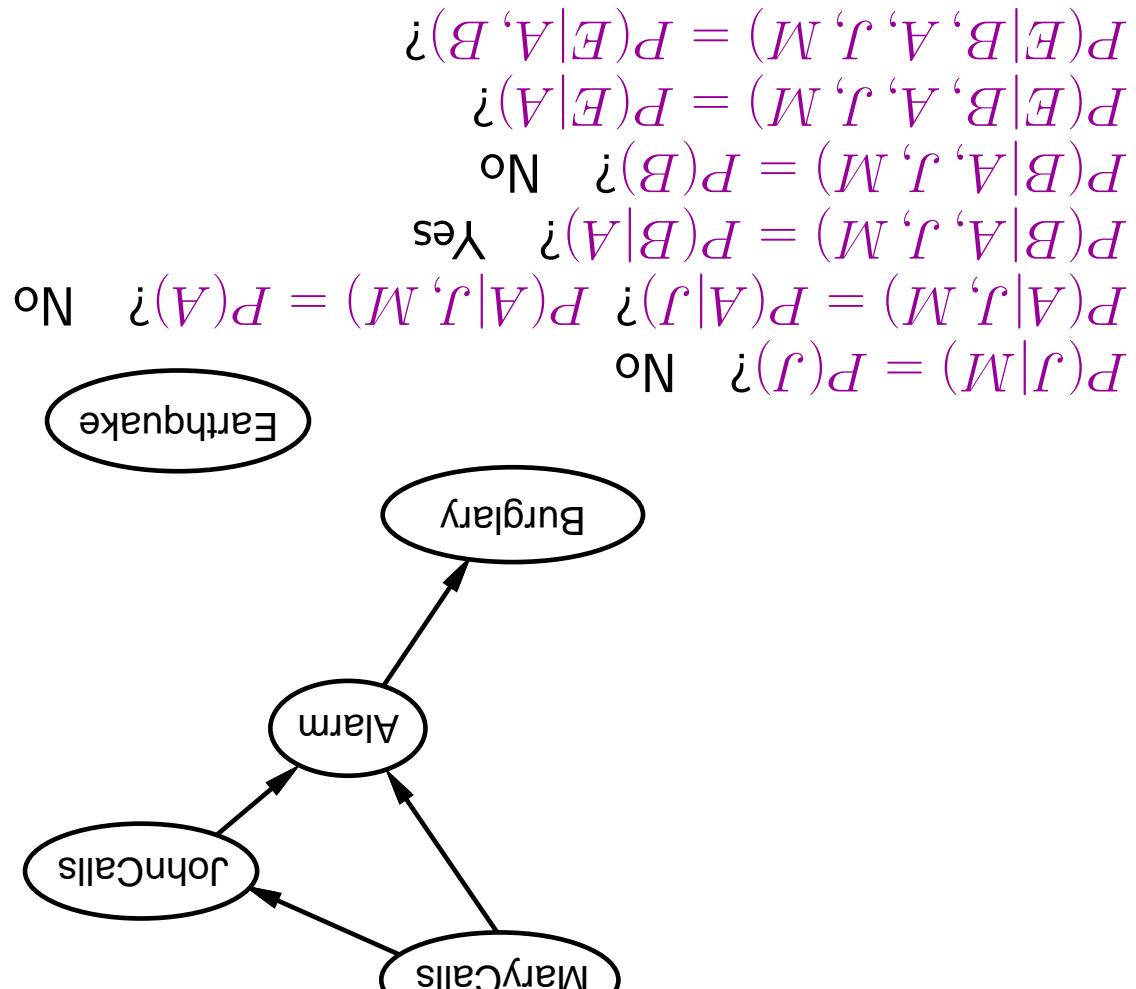

## Example

$P(B|A, J, M) = P(B)$ ?  
 $P(B|A, J, M) = P(B|A)$ ?  
 $P(A|J, M) = P(A|J)$ ?  $P(A|J, M) = P(A)$ ? No  
 $P(J|M) = P(J|F)$ ?  $P(J|M) = (M|J)$ ? No

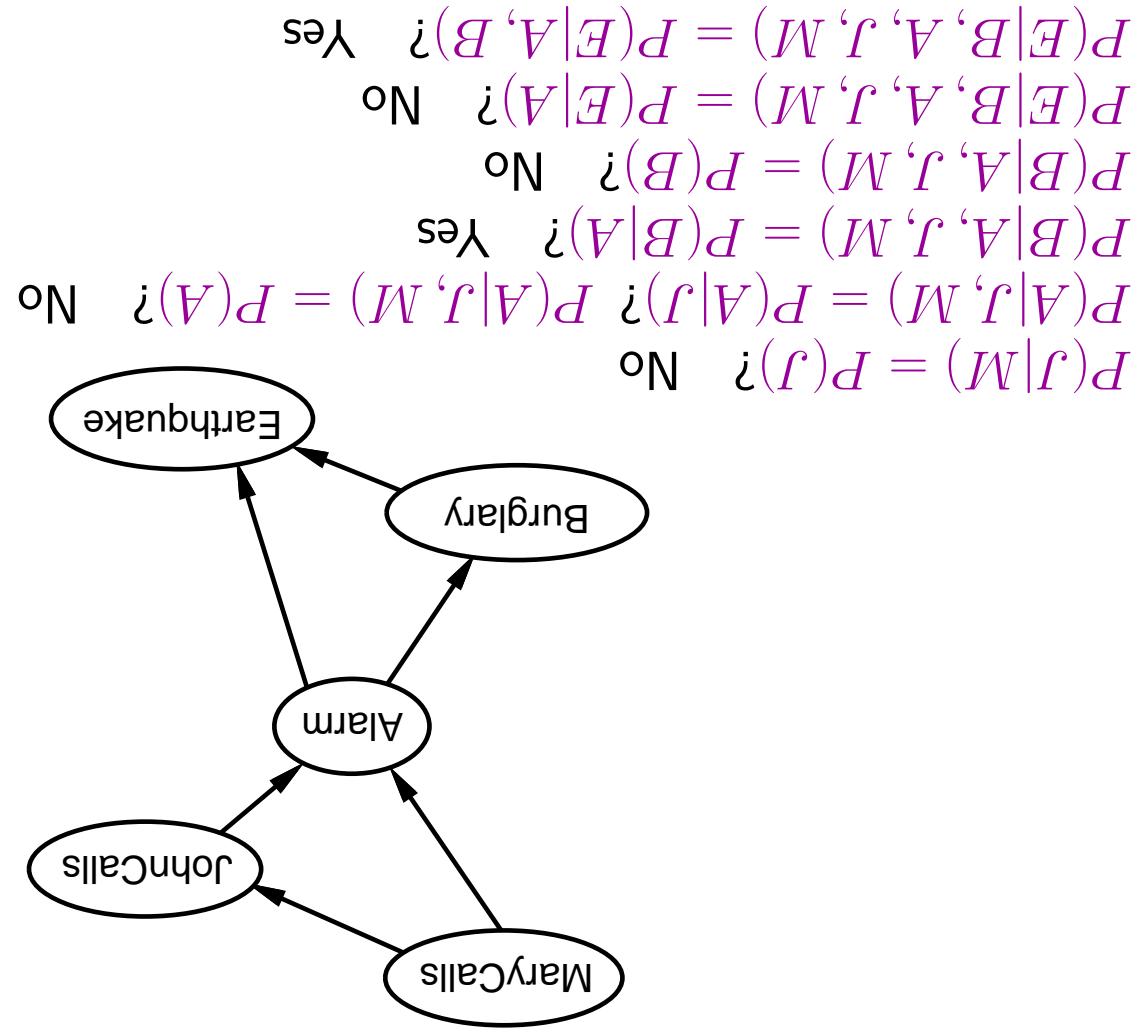

Suppose we choose the ordering  $M, J, A, B, E$

## Example

Suppose we choose the ordering  $M, J, A, B, E$

## Example

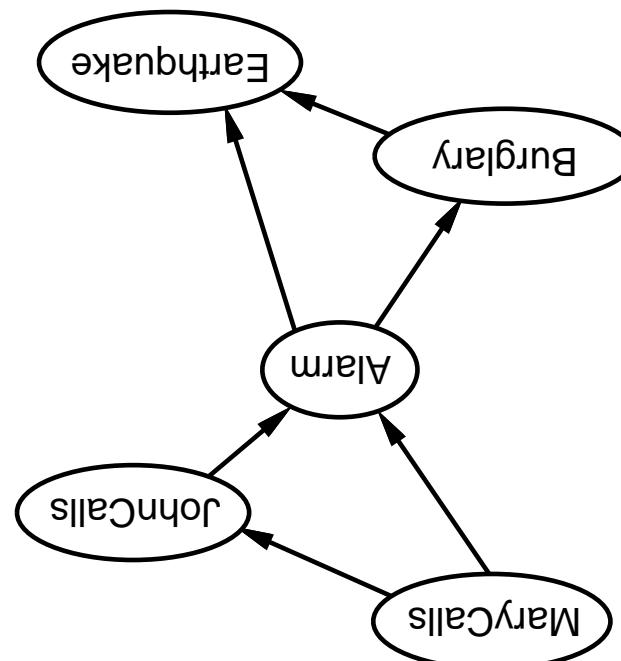

**Example**

Network is less compact:  $1 + 2 + 4 + 2 + 4 = 13$  numbers needed

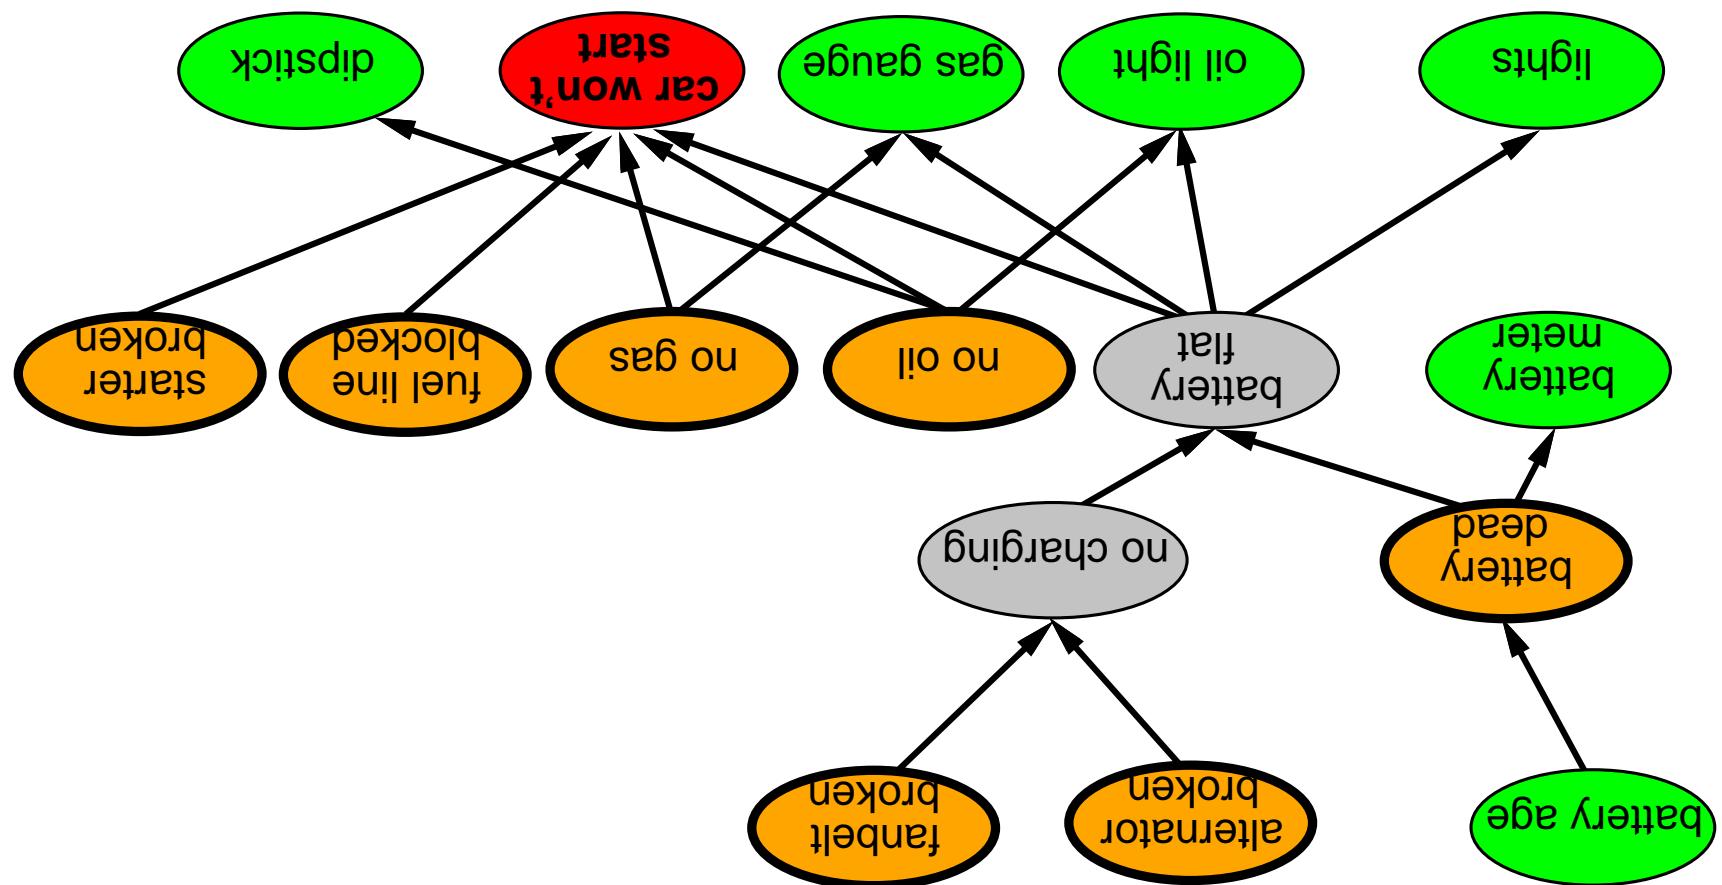

Assessing conditional probabilities is hard in noncausal directions

(Causal models and conditional independence seem hardwired for humans!)

Deciding conditional independence is hard in noncausal directions

Example cont'd.

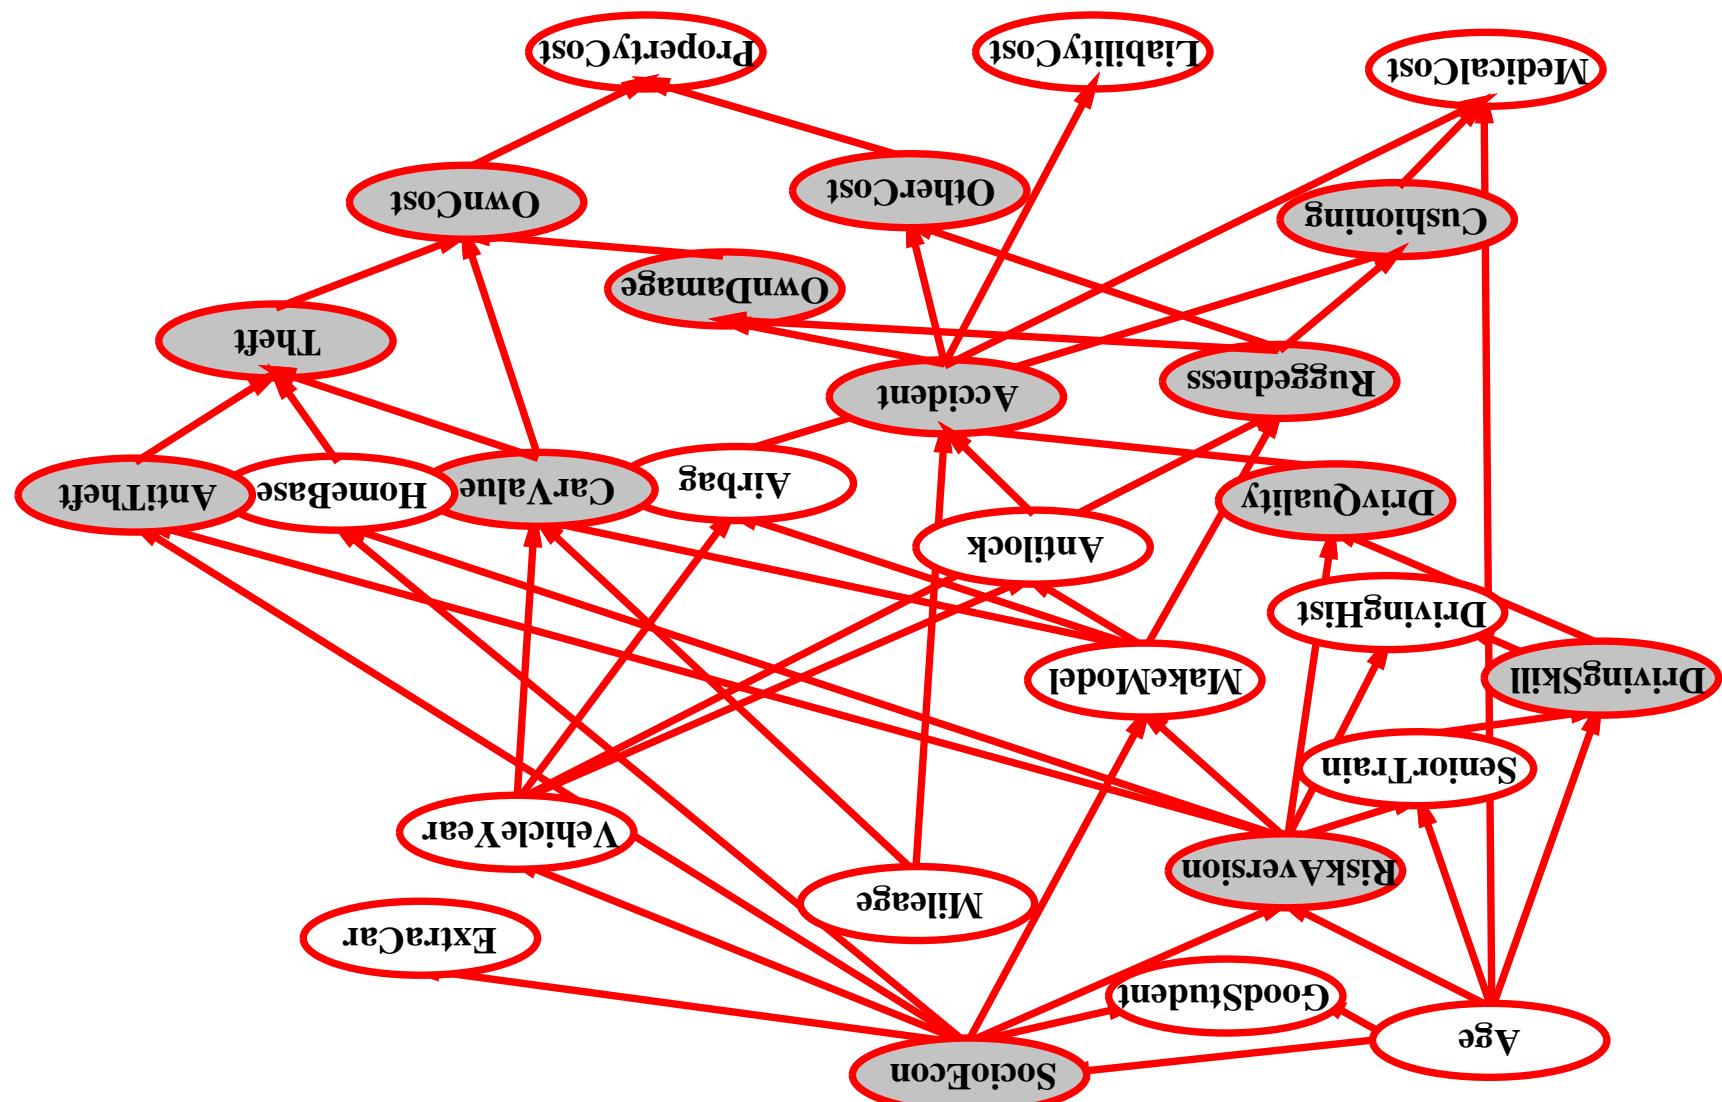

Initial evidence: car won't start

Testable variables (green), "broken", so fix it" variables (orange)

Hidden variables (gray) ensure sparse structure, reduce parameters

## Example: Car diagnosis

Example: Car insurance

$$\frac{\partial h}{\partial t} = \text{inflow} + \text{precipitation} - \text{outflow} - \text{evaporation}$$

E.g., numerical relationships among continuous variables

*NorthAmerican*  $\Leftrightarrow$  *Canadian*  $\vee$  *US*  $\vee$  *Mexican*

E.g., Boolean functions

$$X = f(\text{Parents}(X)) \text{ for some function } f$$

Deterministic nodes are the simplest case:

Solution: canonical distributions that are defined compactly

CPT becomes infinite with continuous-valued parent or child

CPT grows exponentially with number of parents

## Compact conditional distributions

Number of parameters **Linear** in number of parents

| $P(\neg F_{ever})$ | $P(F_{ever})$           | $Malaria$ | $Flu$ | $Cold$                              |
|--------------------|-------------------------|-----------|-------|-------------------------------------|
| 1.0                | 0.0                     | 0.1       | 0.2   | 0.6                                 |
| 0.9                | 0.1                     | 0.4       | 0.98  | 0.02 = $0.2 \times 0.1$             |
| 0.8                | 0.2                     | 0.4       | 0.98  | 0.02 = $0.2 \times 0.1$             |
| 0.94               | 0.06 = $0.6 \times 0.1$ | 0.94      | 0.88  | 0.12 = $0.6 \times 0.2$             |
| 0.98               | 0.02 = $0.2 \times 0.1$ | 0.98      | 0.88  | 0.012 = $0.6 \times 0.2 \times 0.1$ |
|                    |                         |           |       |                                     |

$$\Leftarrow P(X|U_1 \dots U_j, \neg U_{j+1} \dots \neg U_k) = 1 - \prod_{i=j+1}^k p_i$$

2) Independent failure probability  $p_i$  for each cause alone

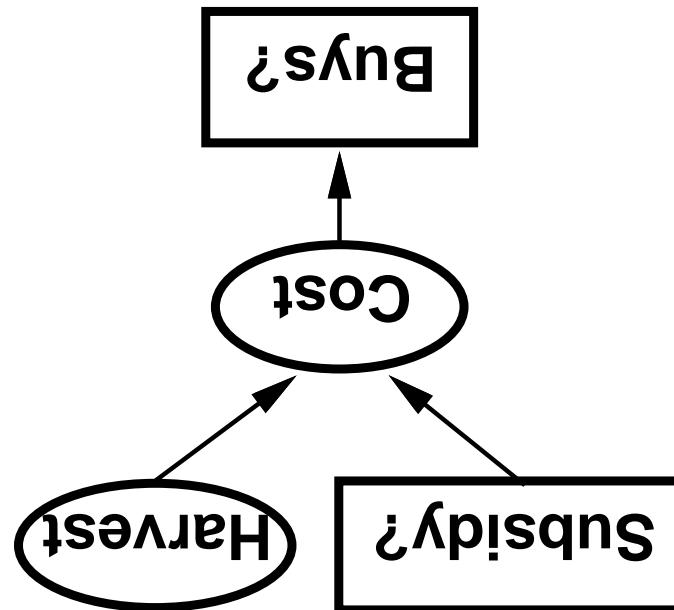

1) Parents  $U_1 \dots U_k$  include all causes (can add leak node)

Noisy-OR distributions model multiple noninteracting causes

Compact conditional distributions contd.

- 1) Continuous variable, discrete+continuous parents (e.g., *Cost*)
- 2) Discrete variable, continuous parents (e.g., *Buyer?*)

Option 1: discretization—possibly large errors, large CPTs  
 Option 2: finitely parameterized canonical families

Discrete (*Subsidy?* and *Buyer?*); continuous (*Harvest?* and *Cost*)

**Hybrid (discrete+continuous) networks**

Linear variation is unreasonable over the full range  
but works OK if the **likely** range of *Harvest* is narrow

Mean *Cost* varies linearly with *Harvest*, variance is fixed

$$= \frac{1}{\sigma_t \sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\frac{(x - (a_t h + b_t))^2}{2\sigma_t^2}} dx$$

$$= N(a_t h + b_t, \sigma_t^2)$$

$$P(Cost = c | Harvest = h, Subsidy? = true)$$

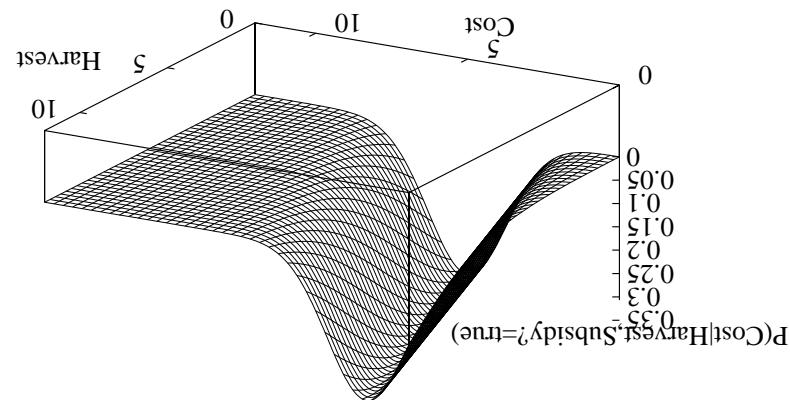

Most common is the **linear Gaussian** model, e.g.:

Need one **conditional density** function for child variable given continuous parents, for each possible assignment to discrete parents

## Continuous child variables

Discrete+continuous LG network is a conditional Gaussian network i.e., a multivariate Gaussian over all continuous variables for each combination of discrete variable values

All-continuous network with LG distributions  $\Leftarrow$  full joint distribution is a multivariate Gaussian

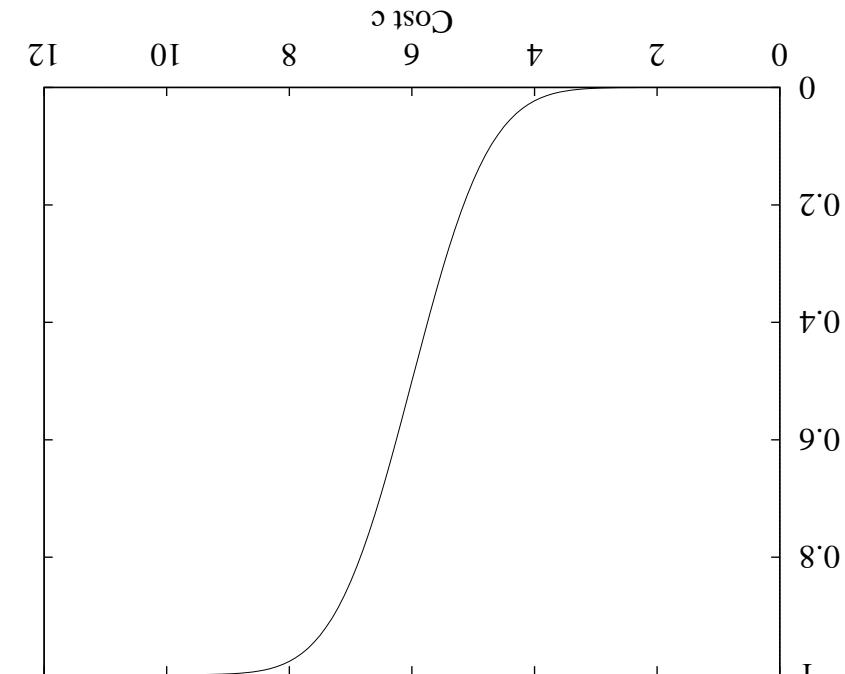

Continuous child variables

$$P(\text{Buys?} = \text{true} \mid \text{Cost} = c) = \Phi\left(\frac{-c + \mu}{\sigma}\right)$$

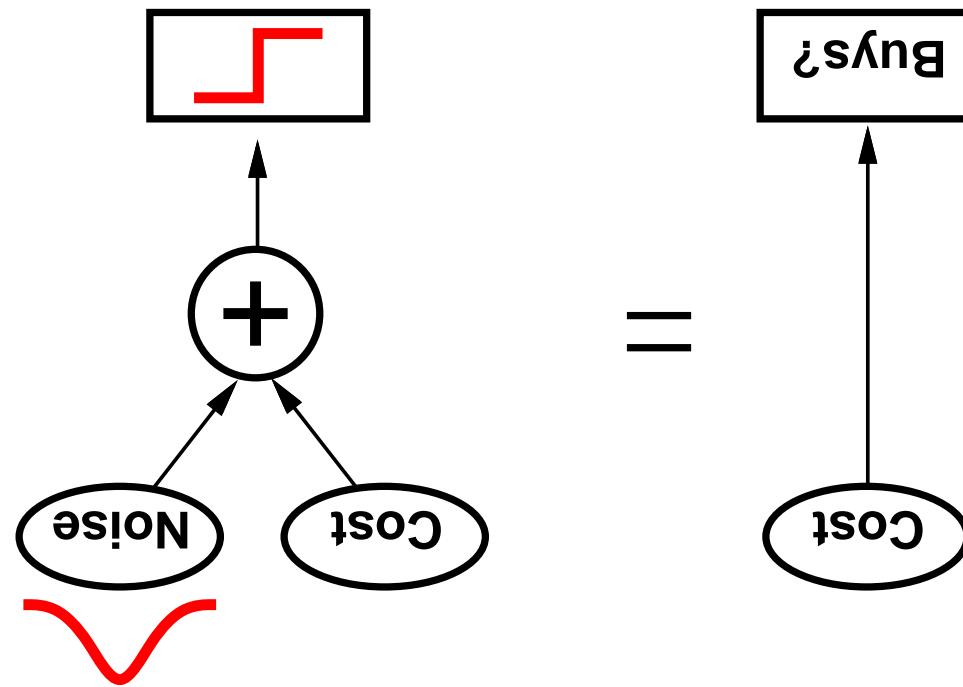

$$\Phi(x) = \int_x^{-\infty} N(0, 1)(x) dx$$

Probit distribution uses integral of Gaussian:

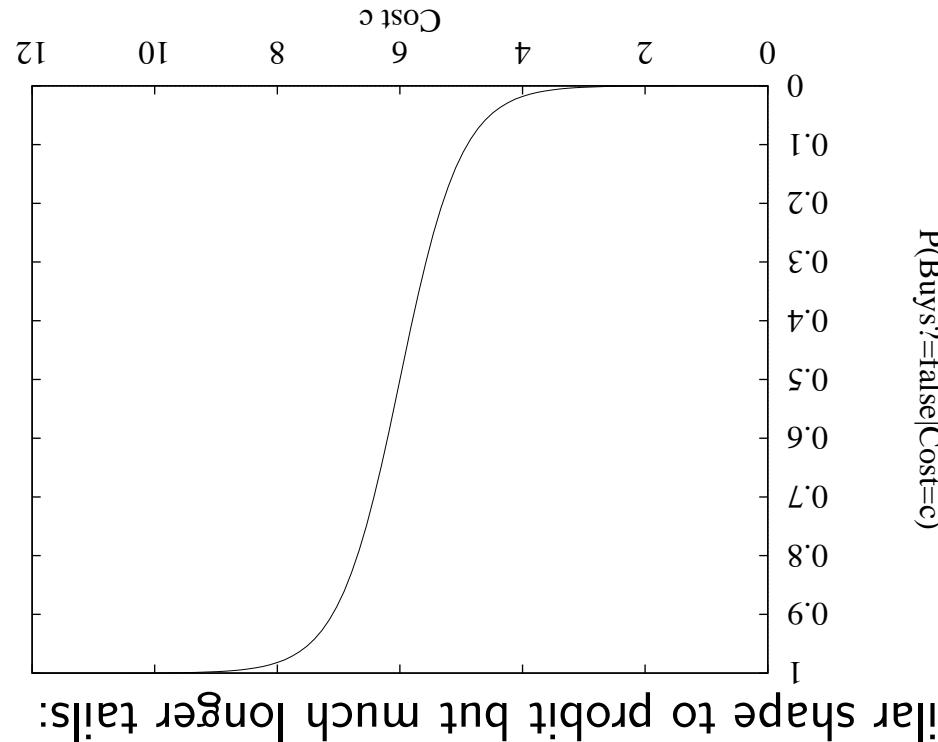

Probability of  $\text{Buys?}$  given  $\text{Cost}$  should be a "soft" threshold:

Discrete variable w/ continuous parents

1. It's sort of the right shape
2. Can view as hard threshold whose location is subject to noise

Why the probit?

$$P(\text{Buys?} = \text{true} \mid \text{Cost} = c) = \frac{1 + \exp(-\frac{c - \mu}{\sigma})}{1}$$

Sigmoid (or logit) distribution also used in neural networks:

**Discrete variable cont'd.**

Bayes nets provide a natural representation for (causally induced) conditional independence

Topology + CPTs = compact representation of joint distribution

Generally easy for (non)experts to construct

Canonical distributions (e.g., noisy-OR) = compact representation of CPTs  
Continuous variables  $\Rightarrow$  parameterized distributions (e.g., linear Gaussian)

## Summary
